Introduction

Stigma is a formidable barrier to the treatment and rehabilitation of patients with mental illness or HIV/AIDS, even among young persons. In contrast with HIV/AIDS, efforts by Nigerian policy makers to reduce the stigma associated with mental illness are virtually non-existent. Information on the attitude of school children towards affected individuals is essential in placing the need to combat the stigma associated with these disorders in the right perspective.

Objectives/Aim

This study determined the social distance of a sample of secondary school students in Nigeria towards individuals with mental illness, as compared with those with HIV-AIDS.

Method

A cross-sectional comparative survey. Secondary school students (n=170) in Lagos, Nigeria completed the modified Borgaadius Social distance Scale.

Results

The respondents were more likely to be socially distant from patients with mental illness than those with HIV/AIDS (p<0.001, 95% CI, 2.56-8.24). About seven out of ten (71.6%) and 20.6% of the participants would be afraid to have a conversation with someone who has mental illness and HIV/AIDS respectively (p<0.001). Those unwilling to be in the same classroom with a student that has mental illness and HIV/AIDS were 74.7% and 17.6% respectively (p<0.001). Less than a tenth (9.4%) could maintain friendship with someone who has mental illness.

Conclusion

The findings suggest that secondary school students in Nigeria desire a higher level of social distance from individuals with mental illness than those with HIV/AIDS. Interventions targeted at reducing the stigma associated with mental illness among school children deserve priority attention.
